ALTITUDINAL RANGE IN LATITUDE RULE IN SOUTHERN AFRICAN FLAT-BACKED MILLIPEDES (PARADOXOSOMATIDAE)

M. COOPER
City of Johannesburg

***Abstract*- The relationship between altitude and range in latitude was investigated in the southern African Paradoxosomatidae millipedes. Altitude and range in latitude were tabulated in 12 species of the southern African Paradoxosomatidae and correlated with each other. A significant correlation between altitude and range in latitude was given in the southern African Paradoxosomatidae (Pearson's r=0.52600518, Z score=1.75381832, n=12, p=0.03973078). This showed that a lower range in latitudes was associated with higher altitudes in the southern African Paradoxosomatidae, as stated in the rule. Narrow ranges in latitude were found above 400 m. All the wider ranges in latitude were found at 783 m (in Namibia) or below 400 m. The absence of the rule was established in the six families of southern African millipedes, viz. Dalodesmidae, Gomphodesmidae, Spirostreptidae, Pachybolidae, Harpagophoridae, Odontopygidae, and the millipede order Spirostreptida, as well as the superorder Juliformia in the southern African subregion, wherein the range in latitude-latitude rule was found. The absence of the rule was also established in a control clade consisting of the Polyxenida, Sphaerotheriidae, and Polyzoniida, wherein the range in latitude-latitude rule was not found in the same southern African subregion.**

I. INTRODUCTION

There are some 558 millipedes in southern Africa belonging to the class Diplopoda. 12 species belong to the Paradoxosomatidae. Paradoxosomatidae, the only family in the suborder Paradoxosomatidea (also known as Strongylosomatidea), is a family of flat-backed millipedes in the order Polydesmida. Containing 198 genera and 975 species as of 2013, it is one of the largest families of millipedes. Paradoxosomatids occur on all continents except Antarctica, and can generally be distinguished by dorsal grooves on most body segments and a dumbbell-shaped gonopod aperture. Groups within the Paradoxosomatidae include the dragon millipedes of Southeast Asia and the widely introduced greenhouse millipede *Oxidus gracilis*.

A correlation between altitude and range in latitude is an ecogeographical rule that states that latitudinal ranges of plants and animals are generally different at higher altitudes than at lower altitudes. This is tested in the southern African Paradoxosomatidae in this paper.

II. MATERIALS AND METHODS

Latitude GPS co-ordinates were obtained for 12 species of southern African Paradoxosomatidae millipedes from localities in a checklist of southern African millipedes and correlated with the altitudes for the respective localities using https://www.gigacalculator.com/calculators/correlation-coefficient-calculator.php. This was repeated in the Dalodesmidae, Gomphodesmidae, Spirostreptidae, Spirostreptida, Pachybolidae, Harpagophoridae, Odontopygidae, and Juliformia. And again in the control clade consisting of Polyxenida, Sphaerotheriidae, and Polyzoniida (individually and as two clades ((Polyxenida and Sphaerotheriidae) and (Polyxenida, Sphaerotheriidae, and Polyzoniida)). In both clades all representatives of southern African species were included. Tests for namal distribution were performed at https://www.statskingdom.com/kolmogorov-smirnov-test-calculator.html first on altitude and then if necessary on range in latitude.

III. RESULTS

Results of the Kolmogorov test indicated that there is a non-significant difference from the normal distribution in altitude (D(12) = 0.24, p = 0.403). Results of the Kolmogorov test indicated that there is a non-significant difference from the normal distribution in the range of latitude (D(12) = 0.29, p = 0.233). Because both were normal, a Pearson's correlation was observed. A significant correlation between altitude and range in latitude was given in the southern African Paradoxosomatidae (Figure 1: Pearson's r=0.52600518, Z score=1.75381832, n=12, p=0.03973078). Mean range in latitude was -12.8355 degrees, standard deviation was 12.9100 degrees, and range was -27.213 degrees to 0.000 degrees. Altitude mean was 521.6667 m, standard

deviation was 617.8993 m, and range was 1.000 m to 1863.000 m.

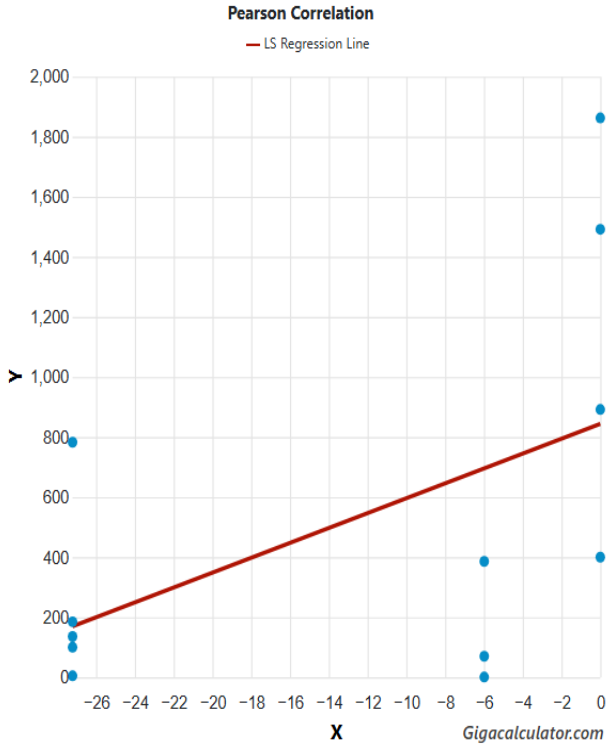

Figure 1. Correlation showing altitude (Y) against range in latitude (X) for the southern African Paradoxosomatidae Daday, 1889.

Narrow ranges in latitude were found above 400 m. All the wider ranges in latitude were found at 783 m (in Namibia) or below 400 m (Figure 1).

Non-significant correlations between range in latitude and altitude were found in the clade consisting of Polyxenida, Sphaerotheriidae, and Polyzoniida (Spearman's r=0.2416, r^2=0.05838, n=61, p=0.05641), Polyxenida and Sphaerotheriidae (r=0.2011, r^2=0.04042, n=57, p=0.134). This was performed because altitude was found to deviate from a normal distribution (D(63) = 0.18, p = 0.0000226) and (D(57) = .18, p = .0000685).

IV. DISCUSSION

Altitude is correlated with range in latitudes in the southern African Paradoxosomatidae. Lower range in latitudes were associated with higher altitudes. A rule is illustrated in southern African Paradoxosomatidae, with data for six genera obtained from a Checklist of Southern African Millipedes, wherein the localities' altitudes were recorded and the range in latitude was calculated. This is seen as a presence of a correlation between the two factors. The lower the altitude, the higher the range in latitude, and the higher the altitude, the lower the range in latitude. This is the first and only southern African family where the rule is known. The absence of the rule was established in the six families of southern African millipedes, viz. Dalodesmidae, Gomphodesmidae, Spirostreptidae, Pachybolidae, Harpagophoridae, Odontopygidae, and the millipede order Spirostreptida, as well as the superorder Juliformia in southern Africa, wherein the range in latitude-latitude rule was found (but this was not subjected to a cladistic analysis). The absence of the rule was also established in a control clade consisting of the Polyxenida, Sphaerotheriidae, and Polyzoniida, wherein the range in latitude-latitude rule was not found. The presence of this rule in the southern African Paradoxosomatidae is easily explained by the family's cosmopolitan distribution and consequent adherence to the rule. The presence of this family in the southern Africa subregion provides us with a global indicator and yardstick of range in latitude and altitude. This has successfully been achieved at high altitude dwelling millipedes [2].
